## The mouse as model for human disease

Why mice?

Gene and protein expression analysis methods

Methods to study gene function in mice *in vivo*

# Why is the mouse used as an experimental animal in developmental biology?

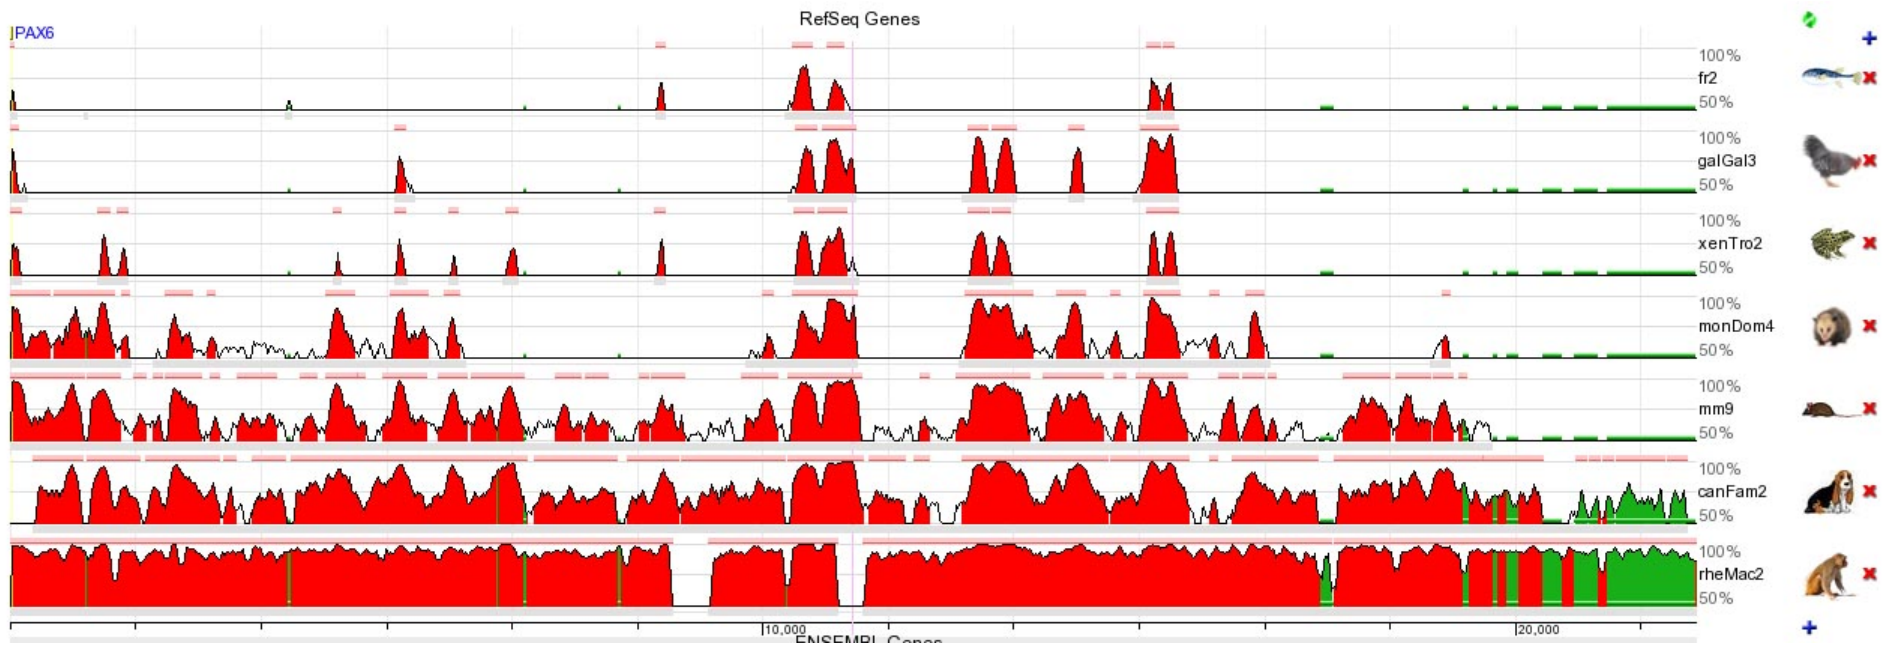

- Small, cheap to house and feed, breed quickly.
- Embryology resembles that of humans.
- Genetically similar to humans.
- Fully sequenced genome.
- Amenable to genetic manipulation.

# Mouse and human embryology are very similar

# Mice are genetically similar to humans

Sequence homology not as good as monkeys, but much better than chick, fish, frogs

# Mouse genome is fully sequenced

Genome sequence of the mouse was complete in 2002  
C57Bl

There are about 23.000 mouse genes

99% of mouse genes have human orthologues

Understand human biology and disease

Gene hunting:

Identification of mutated genes in diseases

*'In silico'* gene identification

# Mouse amenable to genetic manipulation

Mouse gene loss and gain-of-function studies

# What can we do with a mouse to address developmental biology questions?

1. Gene and protein expression analyses
2. Gene function analyses

# Gene and protein expression analysis methods

# Gene and protein expression analysis methods

## Detection of **protein** expression:

- Immunodetection
- Proteomics

## Detection of **RNA** expression:

- RTPCR
- Quantitative RT PCR
- In situ hybridization
- Microarrays

# Protein expression analyses

## Immunodetection

### PAGE and Western Blotting

Electrophoresis

Electroblotting

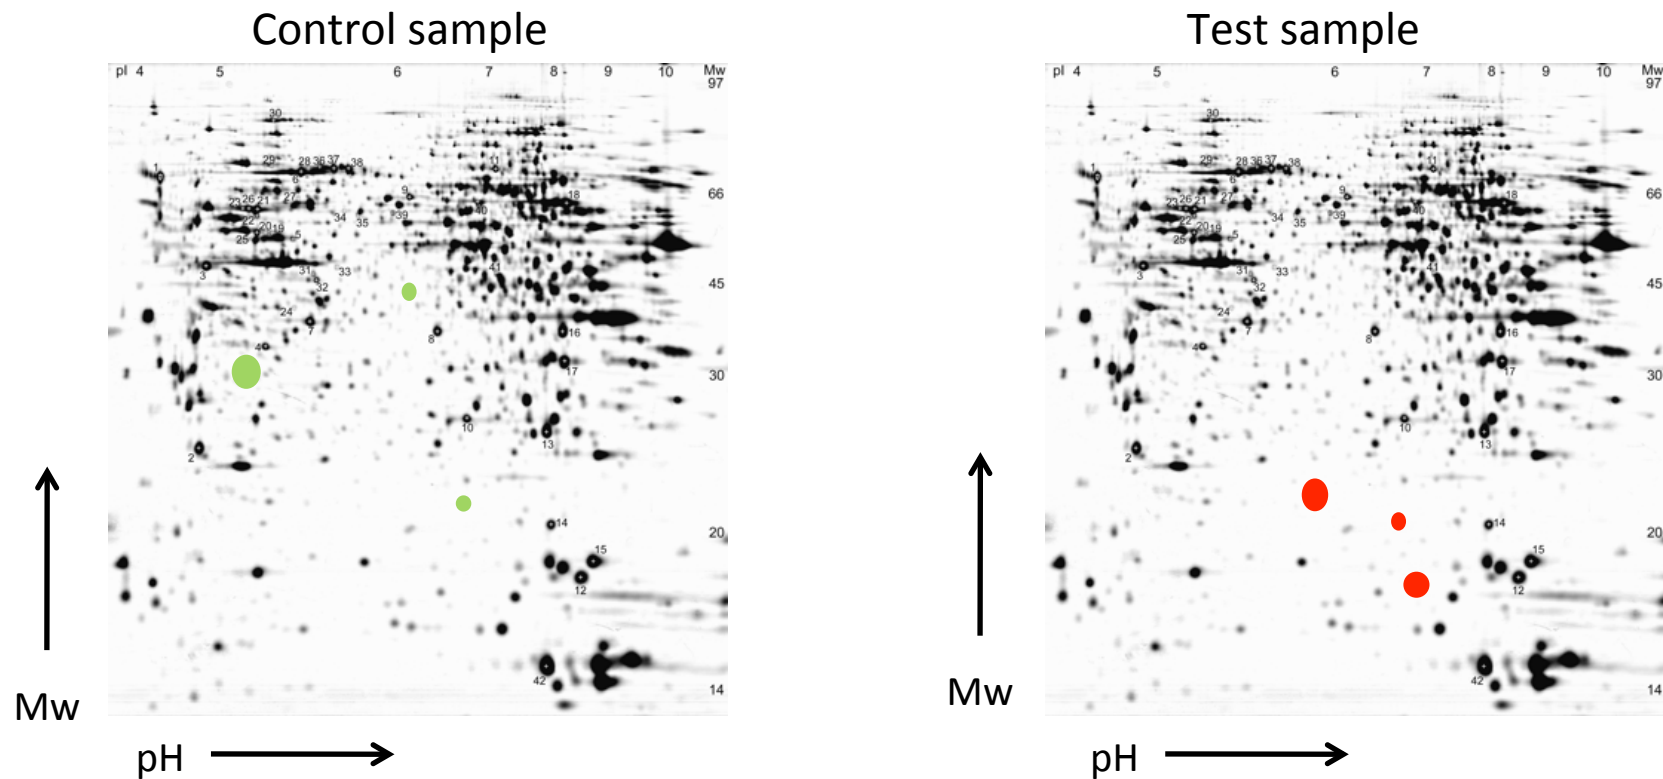

# Protein expression analyses

## Immunodetection

### Proteomics

Large scale study of protein expression

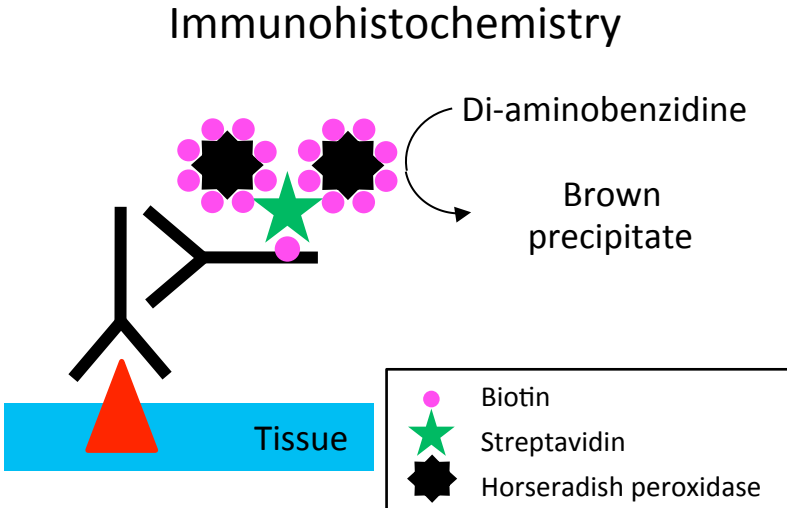

Compare proteomes in biological samples using 2D gels

# Protein expression analyses

## Immunodetection: IHC and IF

**Immunohistochemistry**

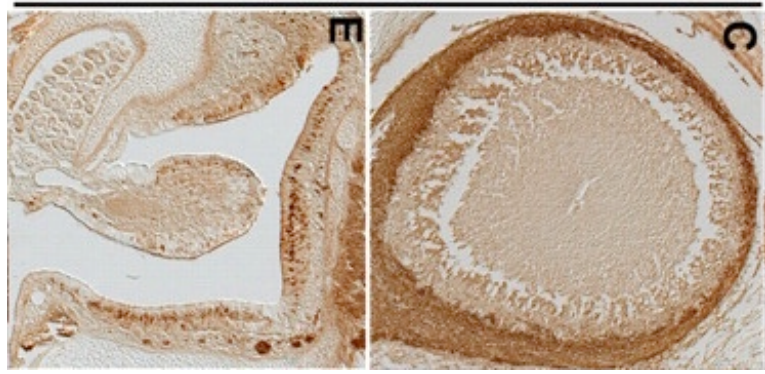

The diagram illustrates the mechanism of immunohistochemistry. A primary antibody (black Y-shape) is bound to a red triangle representing the tissue. A secondary antibody (black Y-shape) is bound to the primary antibody and carries a biotin (pink dot) and a streptavidin (green star). The streptavidin is bound to a complex of horseradish peroxidase (black star) and di-aminobenzidine (pink dots). The reaction of di-aminobenzidine with the enzyme produces a brown precipitate.

Di-aminobenzidine  
Brown precipitate

Tissue

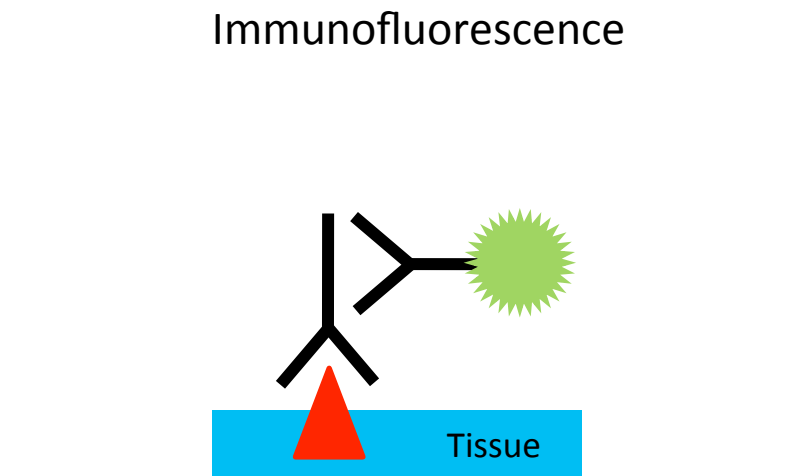

- Biotin
- Streptavidin
- Horseradish peroxidase

**anti-OMP**

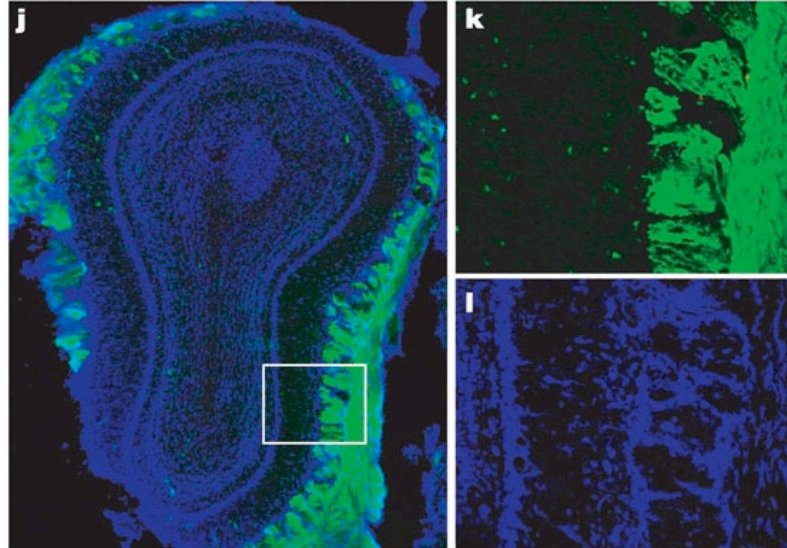

Micrographs showing anti-OMP staining in tissue sections. Panel m shows a low-magnification view of a tissue section with brown staining. Panel n shows a high-magnification view of a tissue section with brown staining.

**Immunofluorescence**

The diagram illustrates the mechanism of immunofluorescence. A primary antibody (black Y-shape) is bound to a red triangle representing the tissue. A secondary antibody (black Y-shape) is bound to the primary antibody and carries a green fluorescent label.

Tissue

Fluorescence microscopy images showing anti-OMP staining in tissue sections. Panel j shows a low-magnification view of a tissue section with green and blue staining. Panel k shows a high-magnification view of a tissue section with green and blue staining. Panel l shows a high-magnification view of a tissue section with blue staining.

# Gene expression analyses

## RT PCR

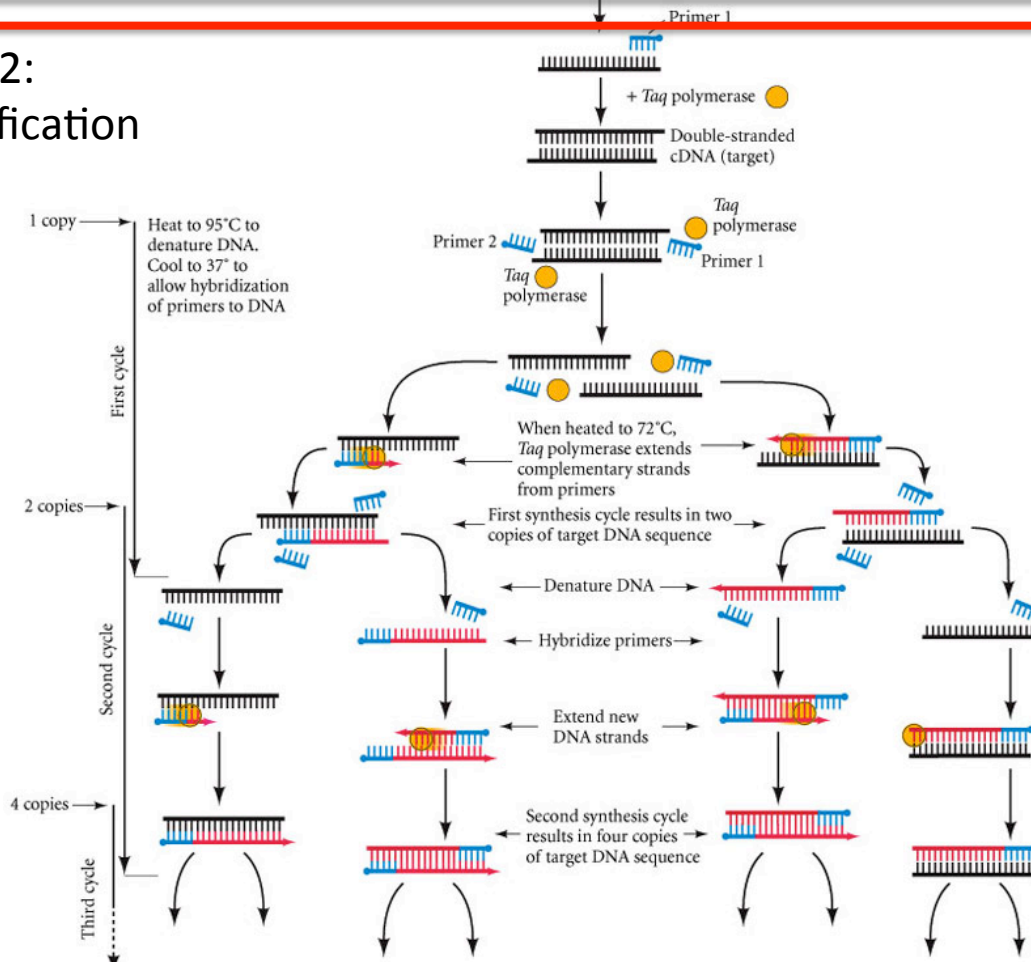

### Step 1

Reverse transcription,  
Generation of cDNA

### Step 2:

PCR amplification

# cycles

# Gene expression analyses

## RT PCR

### Example experimental results

# Gene expression analyses

## Northern Blotting

Northern blotting (RNA blotting):

- Isolate RNA from tissue of interest
- Run RNA on denaturing gel and blot onto nitrocellulose membrane
- Make radioactively labeled antisense cDNA probe
- Hybridize cDNA probe to RNA on membrane
- Visualize probe binding using photographic film

# Gene expression analyses

## quantitative real time RT PCR

- Used for
  - Quantitative gene expression (both relative and absolute),
  - Genotyping,
  - miRNA analysis
  - SNP analysis,
  - Pathogen detection
- Measures PCR amplification as it occurs
- More sensitive than conventional RTPCR

# Gene expression analyses

## quantitative real time RT PCR

Method:

- Isolate RNA
- Make cDNA with reverse transcriptase
- Carry out PCR with primers to amplify genes of interest and intercalating fluorescent dye SYBR Green or Taqman probes
- Detect fluorescent signal during linear amplification phase as measure for amount of PCR product made

# Gene expression analyses

## quantitative real time RT PCR

Fluorescent signal intensity (Ct) is measure for amount of product

- Quantification of expression levels of:
  - different genes within one RNA sample
  - the same gene in different samples (against a reference 'house hold gene')
- Relative vs absolute quantification (against a known standard)

# Gene expression analyses

## *in situ* hybridization

Prepare labeled antisense RNA probe:

- Digoxigenin (DIG)
- Radioactive label

# Gene expression analyses *in situ* hybridization

On sections:

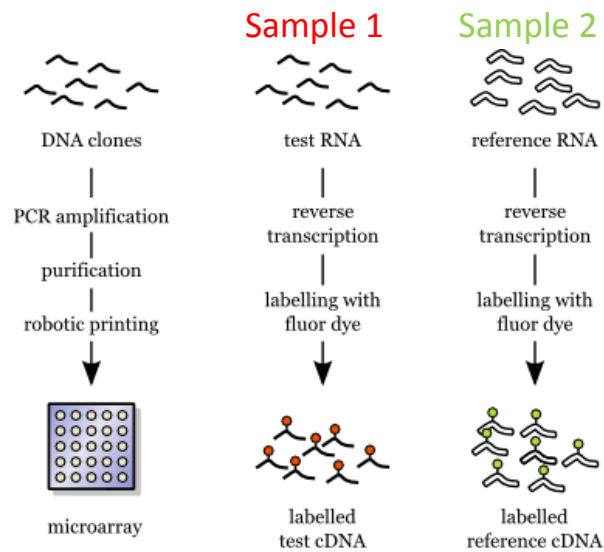

On whole embryos/whole tissues:

# Gene expression analyses

## Expression microarrays

Compare the expression levels of thousands of genes between samples

- cDNAs or gene-specific oligos spotted onto glass slides (arrays).  
(Each dot represents 1 gene)

- Hybridization with 2 fluorescently labeled probes:

**Probe 1:** sample 1 labeled with red label

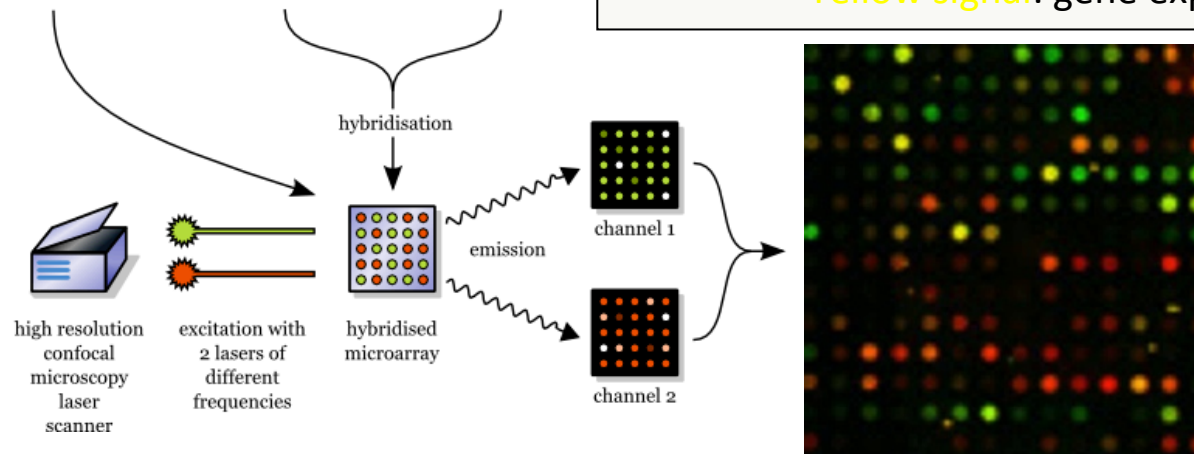

**Probe 2:** sample 2 labeled with green label

- Automated signal quantification:

**Red signal:** gene only expressed in sample 1

**Green signal:** gene only expressed in sample 2

**Yellow signal:** gene expressed in both sample 1 and 2

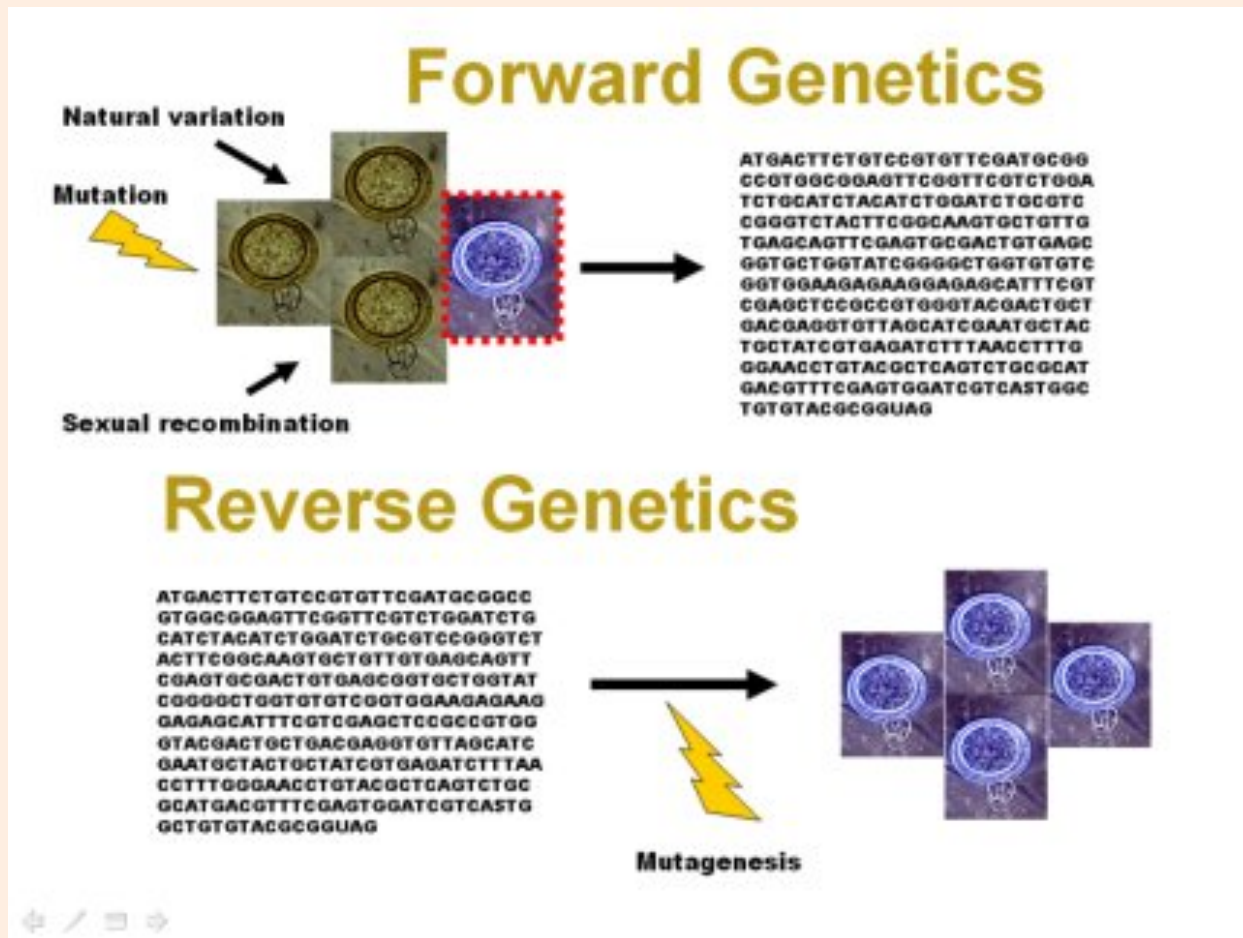

# Expression analyses overview

Method	Detection of	Quantitative	Spatial information	Results within
Protein gel Western blot	Protein	Limited	No/Little	2 Days
IHC/IF	Protein	Limited	Yes	2 Days
Proteomics 2D protein gels	Proteome	Yes	No/Little	Depends
RT PCR	RNA	No	No/Little	1 Day
Real Time PCR	RNA	Yes	No/Little	1 Day
Northern blotting	RNA	Limited	No/Little	Few days
Section <i>in situ</i> hybridization	RNA	Limited	Yes	Few weeks
Whole mount <i>in situ</i> hybridization	RNA	Limited	Yes	1 Week
Expression microarray	Transcriptome	Yes	No/Little	Depends

# Methods of studying gene function

Forward genetics: phenotype -> gene  
Reverse genetics: gene -> phenotype

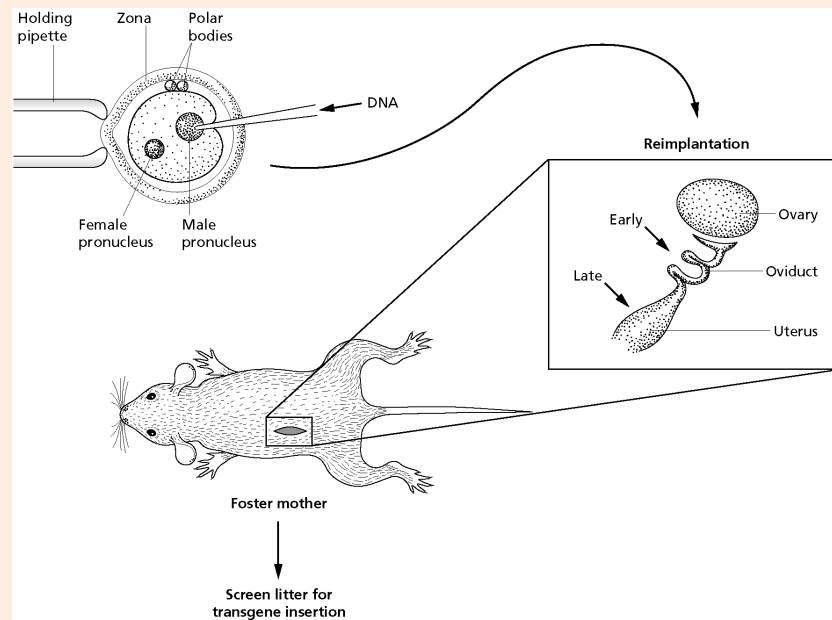

(Random) gene mutagenesis  
*Caenorhabditis elegans*  
*Drosophila melanogaster*  
Zebrafish  
(Mouse)

Gene gain- or loss-of-function  
*Caenorhabditis elegans*  
*Drosophila melanogaster*  
Zebrafish  
**Mouse**

# Gain-of-function transgenesis

## Generation of Transgenic mice:

1. Generate transgenic construct  
NB! promoter + cDNA
2. Inject transgene into zygotes
3. Transgene is integrated into genome
4. Transfer zygotes to pseudopregnant mouse
5. Transgene is expressed by mouse (embryo)

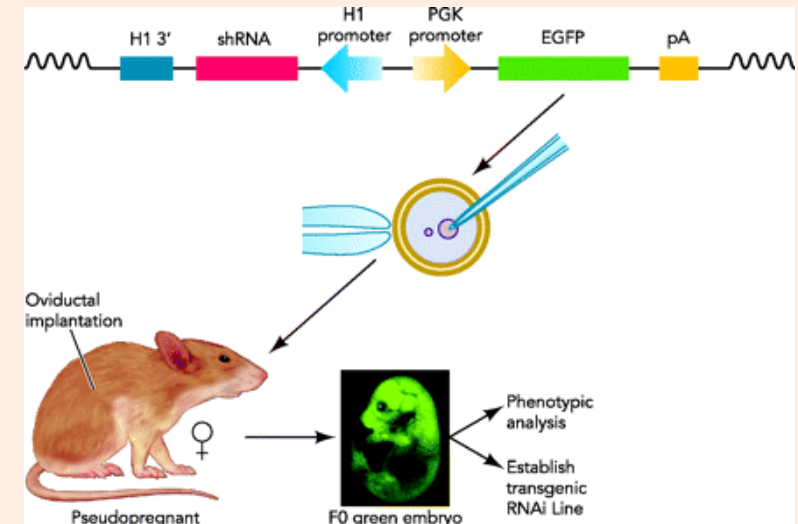

# Loss-of-function transgenesis

## RNA interference

Overexpression of short hairpin RNAs (shRNA) that silence genes of choice

# Knock out technology

Crossing over is a natural process that happens during meiosis

Knock out technology =  
directed homologous recombination in omnipotent ES cells

# Knock out technology

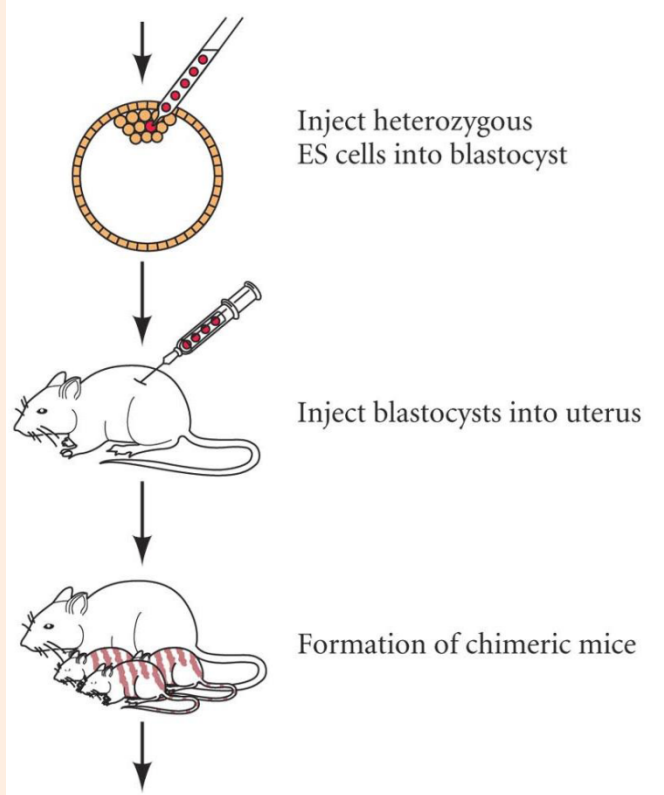

# Knock out technology

# Knock out technology

Heterozygous mutant  
Embryonic stem cells

Chimeric mice

Genetic crosses to obtain  
Homozygous mutant mice

# Knock out technology

## Engineering of targeting vectors

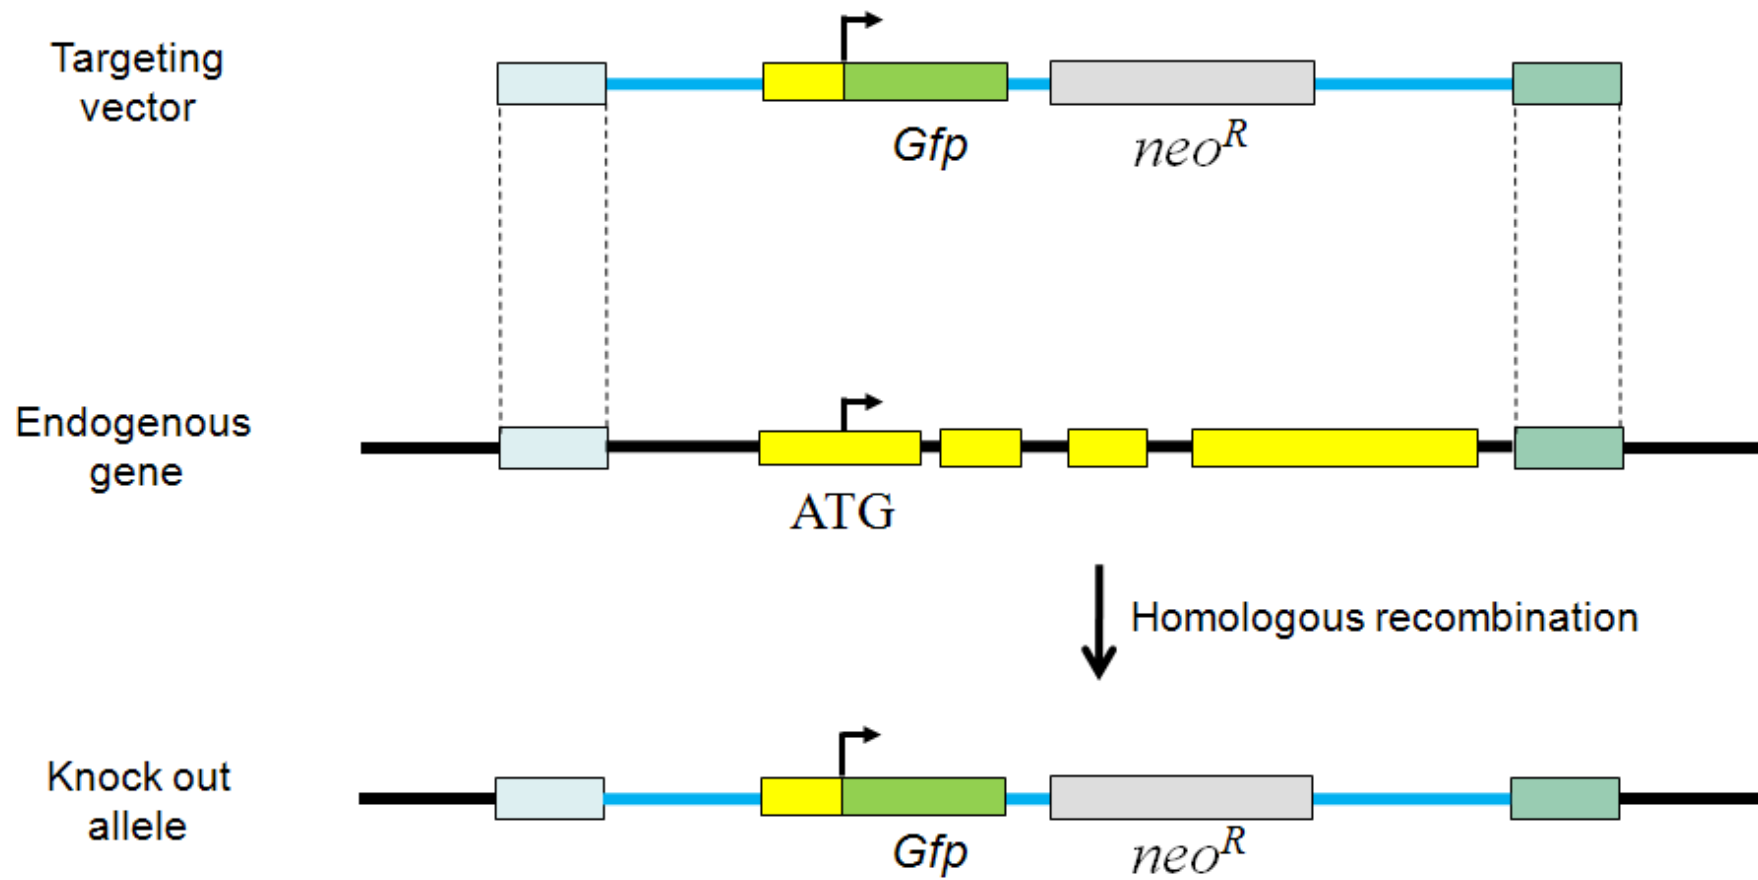

### Generating dominant negative proteins

# Knock out technology

## Engineering of targeting vectors

### Expressing reporter genes from mutant locus

# Knock out technology

## Engineering of targeting vectors

### Gene swapping

# Knock out technology

## Engineering of targeting vectors

### Bicistronic messengers

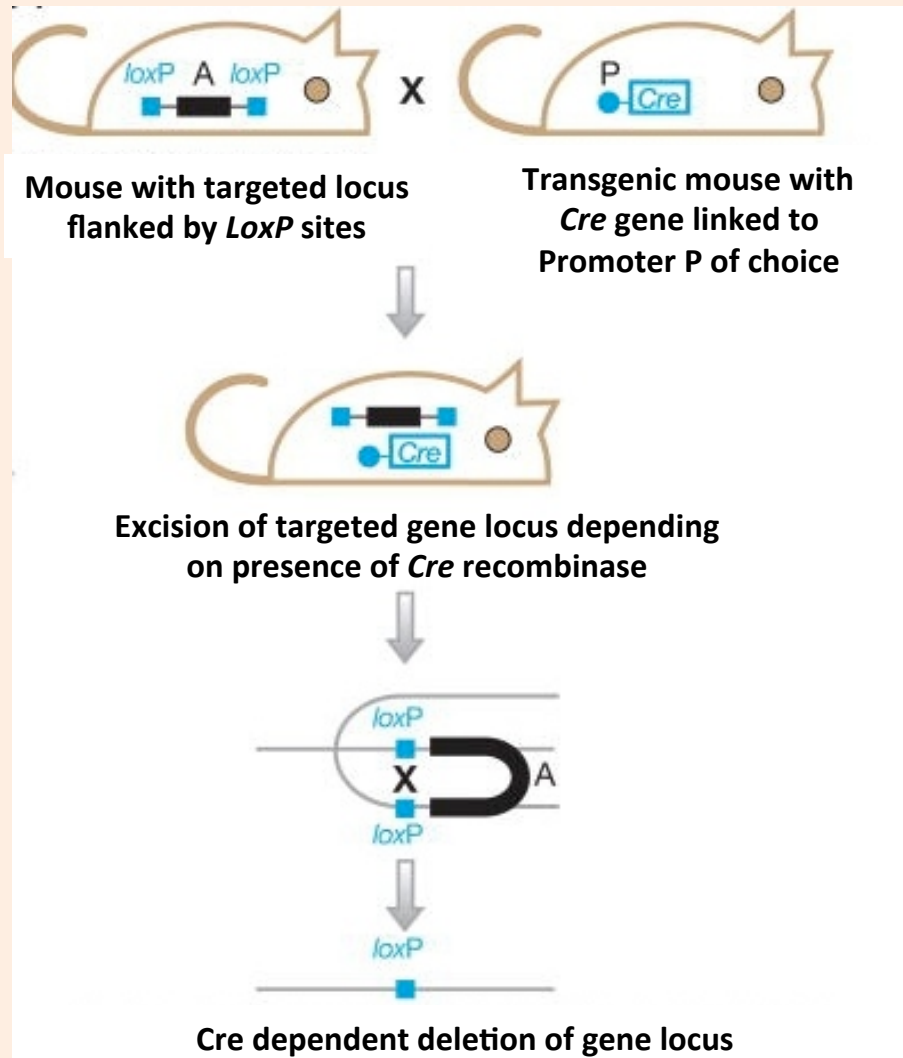

# Conditional knock out technology

Conditional LOF mutants: excision of gene dependent on presence of

- Loxp sites in gene locus
- Cre recombinase

# Conditional knock out technology

## Advantages:

Cell/tissue type specific  
Timing specific  
Inducible

# Random mutagenesis screens

You want to identify new genes that are involved with a certain process

The male animal is subjected to a mutagen, e.g. radiation, or chemical mutagens such as ethylnitrosurea (ENU) or ethylmethyl sulphate (EMS).

Mutagen hits the germ line

Mouse now produces mutant spermatozoa

# Random mutagenesis screens

## A screen for dominant mutations:

Mate mutated mice with wildtype females.

Screen babies for phenotypes.

Those that are heterozygous for a dominant gene will show a phenotype.

# Random mutagenesis screens

## A screen for recessive mutations:

Some of the F1 progeny of the mutagenised mice might LOOK normal, but be heterozygous for a recessive mutation.

Have to breed a litter of progeny then do brother-sister matings to get  $-/-$  mice.

# Random mutagenesis screens

Select mice with desired phenotypes

Start identification of mutated genes:  
Combination of genetic linkage mapping and  
sequencing

# Manipulation of gene function in the mouse

Transgenesis: - gain of function transgenesis  
- reporter overexpression  
- loss of function transgenesis

Mutagenesis: - Conventional knock out mice  
- Conditional knock out mice  
- Random mutagenesis
