 - 5.2 Primitive Streak
 - 5.3 Primitive Node
 - 5.4 Epithelial to Mesenchymal Transition
- 6 Notochord
- 7 Embryo Folding
- 8 Timeline

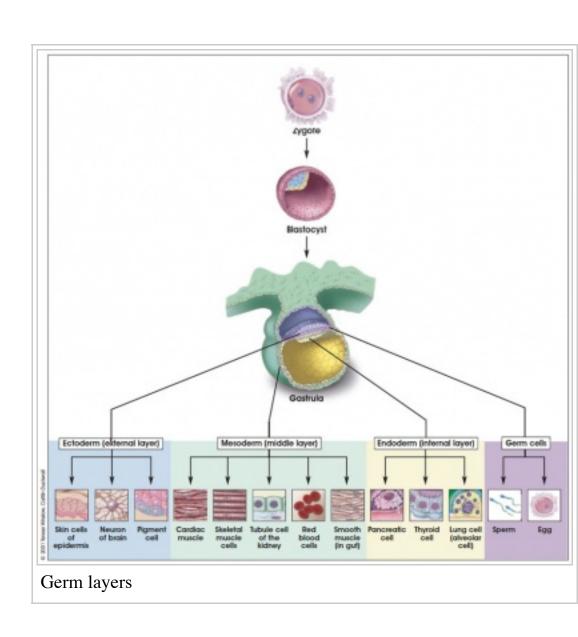

Introduction

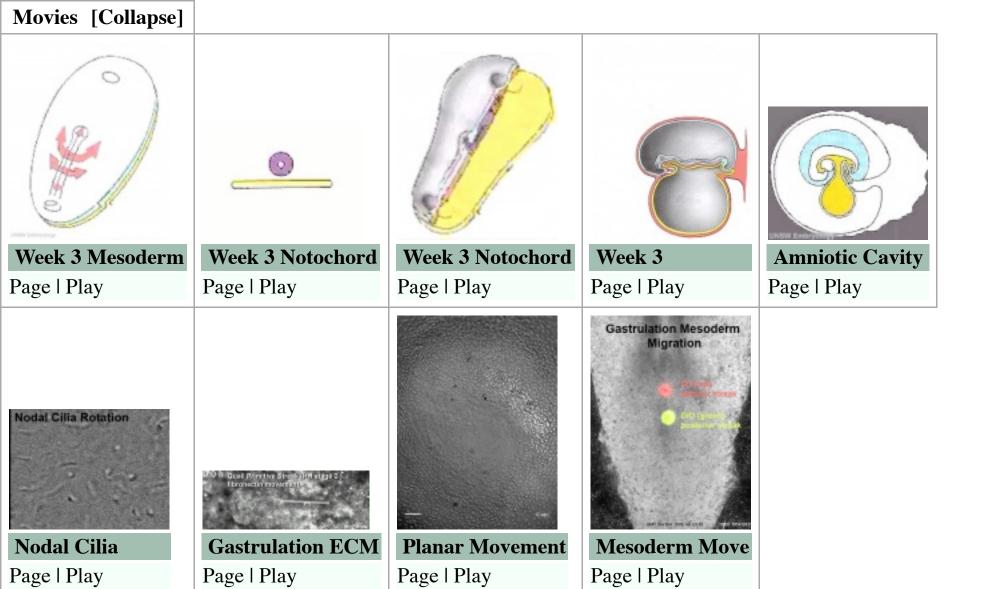

In this lecture I will talk about week 3 of embryonic development. I will cover early placentation, gastrulation and embryonic folding.

Objectives

- Understand the process early placentation, villi formation
- Understand broadly the events of week 3 of human development
- Understand the process of gastrulation
- Understand the process of axis formation
- Brief understanding of embryo folding

Early Placentation

The trophoblast layer has now differentiated into two morphologically distinct cellular layers.

- Syncitiotrophoblasts form a multinucleated cytoplasmic mass by cytotrophoblast cell fusion and both invade the decidua and secrete hCG
- Cytotrophoblasts form a cellular layer around the blastocyst, proliferates and extends behind syncitiotrophoblasts

- transfer of nutrition from maternal lacunae filled with secretions from uterine glands and maternal blood from blood vessels.
- development of trophoblast villi extending into the uterine decidua.
- ongoing process with placental development (covered in future lecture)

There are three stages of villi development:

- 1. Primary Villi cytotrophoblast
- 2. Secondary Villi cytotrophoblast + extraembryonic mesoderm
- 3. Tertiary Villi cytotrophoblast + extraembryonic mesoderm+ blood vessels

There are two main types of early villi:

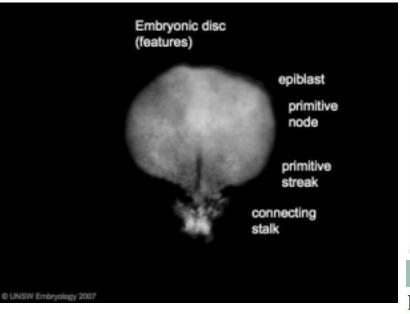

- 1. Anchoring villi attached to decidua
- 2. Floating villi not attached to decidua, floating in maternal lacunae.

Gastrulation

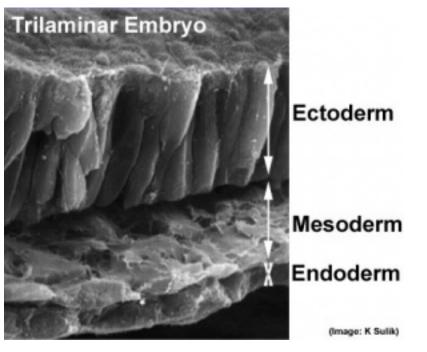

Embryonic Disc

- Gastrulation, (Greek = belly) means the formation of gut.
- used in a more looser sense to to describe the formation of the trilaminar embryo.
- Epiblast layer consists of totipotential cells forming all 3 embryo layers (germ layers) that form the entire embryo.
 - Historically, gastrulation was one of the earliest observable morphological event occurring in the frog embryo.
 - Currently, the molecular and physical mechanisms that regulate patterning and migration during this key event are being investigated in several different animal models.
 - In humans, it is proposed that similar mechanisms regulate gastrulation to those found in other vertebrates.

Embryonic Disc showing primitive streak

- 1. **Ectoderm** (epithelium) forms the central and peripheral nervous system, parts of the sensory systems, and the epithelium of the skin.
- 2. **Mesoderm** (connective tissue) forms the body connective tissues: blood, bone, muscle, connective tissue skin, gastrointestinal and respiratory tracts.
- 3. **Endoderm** (epithelium) forms gastrointestinal tract organs and the epithelium of the gastrointestinal and respiratory tracts.

This is a very simplified explanation of the 3 layer contributions, many body tissues have contributions from all 3 origins.

Early placenta anchoring villi

Primitive Streak

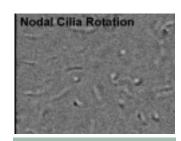

The primitive streak is the visible feature which represents the site of cell migration to form the additional layers.

- Midline of embryonic disc running between the primitive node to near the edge of the disc at the caudal end (near the connecting stalk).
- Region of cell migration from the epiblast layer forming sequentially the two germ cell layers (endoderm and mesoderm).
- Cells that do not migrate form the ectoderm.

primitive node cells migrate ventrally through the primitive streak

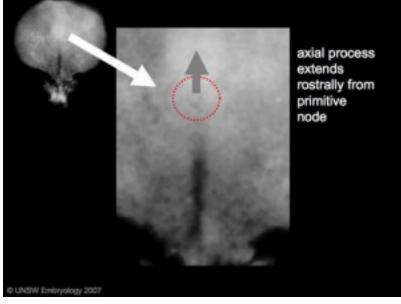

Primitive Node

- (Hensen's node) region in the middle of the early embryonic disc epiblast from which the primitive streak extends caudally (tail).
 - nodal cilia establish the embryo left/right axis
 - axial process extends from the nodal epiblast

Epithelial to Mesenchymal Transition

Chicken Gastrulation An amicable separation: Chick's way of doing EMT. Nakaya Y, Sheng G. Cell Adh Migr. 2009 Apr;3(2):160-3. Epub 2009 Apr 10. PMID: 19262172

Chicken Gastrulation An amicable separation: Chick's way of doing EMT. Nakaya Y, Sheng G. Cell Adh Migr. 2009 Apr;3(2):160-3. Epub 2009 Apr 10. PMID: 19262172

- **Epithelial cells** (organised cellular layer) which loose their organisation and migrate/proliferate as a mesenchymal cells (disorganised cellular layers) are said to have undergone an Epithelial Mesenchymal Transition (EMT).
- Mesenchymal cells have an embryonic connective tissue-like cellular arrangement
 - cells that have undergone this process may at a later time and under specific signaling conditions undergo the opposite process, mesenchyme to epithelia.
- In development, this process can be repeated several times during tissue differentiation.

This process occurs at the primitive streak where epiblast cells undergo an epithelial to mesenchymal transition in order to delaminate and migrate.

MH - there are a number of common cellular changes that occur during embryonic development at different times and in different tissues, which we can classify into "developmental mechanisms".

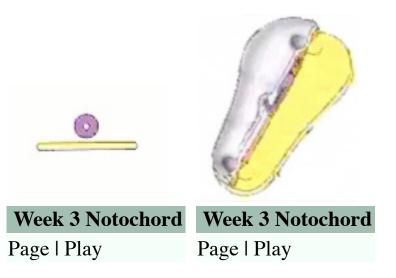

Notochord

• The notochord is a structure which has an early mechanical role in embryonic disc folding and a major signaling role

in patterning surrounding embryonic tissue development.

- A developmental feature not present in the adult anatomy.
- This signaling role patterns many different tissues (neural plate, neural tube, somites, endodermal organs).
- Has own sequence of development from a primitive axial process
 - axial process an initial epiblast hollow epithelial tube which extends in the midline from the primitive pit, cranially in the embryonic disc (toward the oral membrane).
 - **neuroenteric canal** is a transient communication between the amnionic cavity and the yolk sac cavity formed by the axial process.
 - **notochordal plate** forms from the axial process merging with the endoderm
 - **notochord** forms from the notochordal plate which then separates back into the mesoderm layer as a solid column of cells lying in the midline of the embryonic disc and running rostro-caudally (head to tail).
- An alternate name for the notochord is "axial mesoderm".

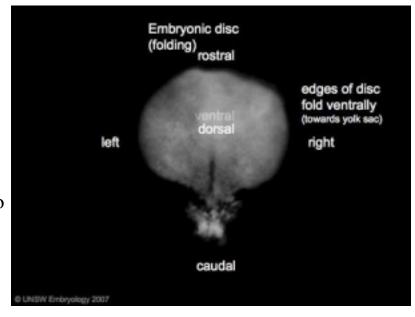

MH - Much of our knowledge of this structure comes from the study of animal models of development.

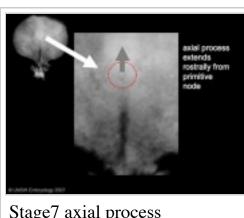

Links: Notochord Movie | Mesoderm

Embryo Folding

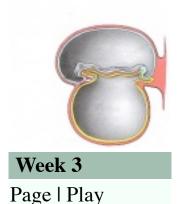

- **embryonic disc** now has 3 germ layers (ectoderm, mesoderm, endoderm)
- this flat 3 layer disc then begins to fold ventrally at the edges
- eventually forming a "hollow tube" of these 3 germ layers

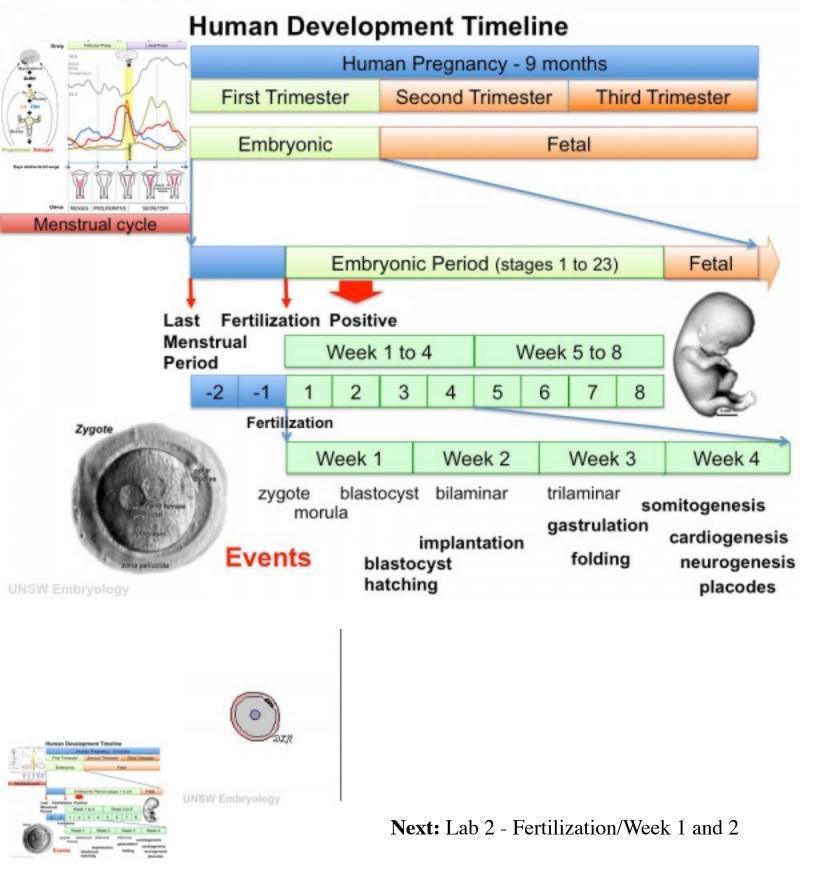

Stage7 axial process
